

DIE & LOCATOR TOOLING GUIDE
500 Series

CRIMPING FACTS

HISTORY OF CRIMPING

Crimping may be defined as the art of joining a conductor to a contact by controlled compression and displacement of metal.

The first methods of crimping multi-pin connectors typically involved soldering the conductor to non-removable contacts. The advent of high temperature and serviceable removable contact applications, together with the need for simple and reliable field service led to crimping the conductor rather than being soldered.

Beginning in the early sixties, a number of Military specifications have been introduced in order to define crimping tool standardization.

MIL-C-22520D is the culmination of these efforts, setting forth a single specification which determines the performance of crimp tools for use on military standard electrical contacts.

CRIMPING CHARACTERISTICS

Connectors utilizing crimping contacts usually permit the removal of these contacts several times so that modification, circuit changes, or replacement of contacts may be made with little difficulty and with the same quality assurance as in production line assembly.

Crimping may be accomplished either with hand tools, power tools, or automated power tools. Repeatability of the crimp operation is characteristic provided precision crimping tools are employed. These tools must be capable of being gaged to insure that proper crimp depths are maintained.

Inspection holes in each contact permit quality control personnel to view the wire strand ends thereby assuring that the conductor is properly positioned in the crimp barrel.

CRIMPING MECHANICS

The goal of a properly designed crimp is to produce a joint with electrical resistance equal to, or less than an equal section of wire. Additionally, the achievement of high tensile strength (mechanical pull-out force) is desired. Both of these crimping characteristics are specified for various connectors in the MIL-C-22520D specification.

In a good crimp joint, there is a mutual metal flow causing symmetrical distortion of wire strands and contact material. The mil cross-sectional area is but slightly reduced and all voids are practically eliminated. Such a joint is similar to a cold weld. Mechanical strength and good electrical continuity are established. Because of the new environments to which electrical connectors are subjected, there has been a drastic change in thinking relative to the use of precision crimp joints in preference to solder.

CRIMPING CONFIGURATIONS

There are many different types of crimps employed today. These range from the terminal fold-over tab type of crimp to the single indent crimp, the dual indent crimp, the three indent crimp, hex crimps, and, finally, the MIL standard four indent crimp. The four indent crimp provides the most uniform displacement of wire and contact material. The wire strands and the contact material are formed together in a solid mass with little or no reduction of the mil area of the wire strands. A minimum of voids exists and very little extrusion of the wire strands has taken place.

The four indent crimp principle has been used to produce a variety of impressions, the most common being the "bathtub" and "octadent" (also called double indent). The octadent configuration has been chosen by the Military for use in the M22520/1 and /2 tools.

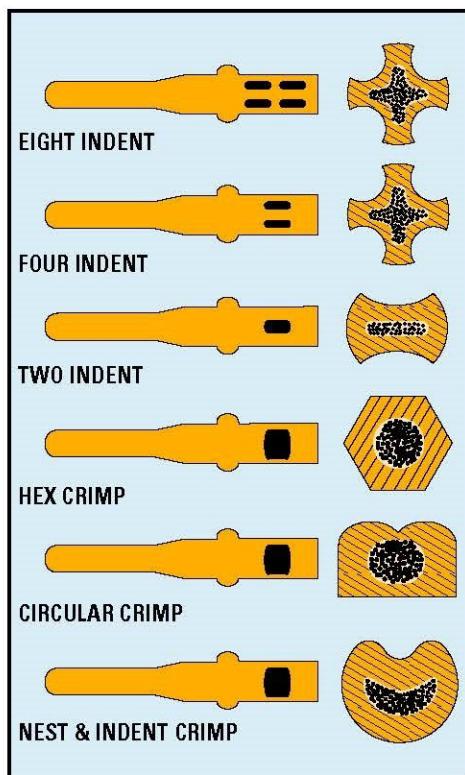

CRIMP DEPTH DETERMINATION

Having resolved an indentor design, the determination of crimp depth range must be established for each application. There are many factors which contribute to the selection of the proper indentor setting. These are primarily related to contact material and dimensions as well as wire type and size.

The proper crimp depth for a given contact is the one that yields the best mechanical and electrical joint. To determine this setting, many contacts of the same type are crimped though a range of indentor settings from too loose to too tight. The crimped contacts are then subjected to tensile and voltage drop tests.

WIRE PREPARATION

Proper wire preparation also plays an important part in making a good crimp joint. There are two popular methods of wire stripping; mechanical and thermal. During the mechanical stripping process, extreme care must

CRIMPING FACTS

be taken to avoid nicking or removing wire strands, otherwise a loss of tensile strength will result. Conversely, if the insulation is not completely removed, erratic values may be obtained. Heat stripping eliminates the danger of nicking strands. However, depending on the type of insulation being stripped, too much heat can cause actual charring of the insulation or decompose the insulation with the evolution of corrosive gases which react with the conductor platings. There is also a possibility of local annealing of the conductor. Too little heat can deposit an insulation film which can act as a lubricant. Any of these conditions can affect tensile results. Wire preparation is, therefore, another area that requires control if proper tensiles are to be achieved with a wire-contact combination.

Before making a tensile test it is also important that the stripped length of the wire be checked to insure that the wire extends all the way into the contact wire barrel. During the tensile test it is necessary for the uncrimped end of the wire to be held in such a way that the pull force is evenly distributed to all the strands.

TENSILE TESTING

Tensile testing is a controlled pull test on the crimp joint to determine its mechanical strength. It is a destructive test which usually results in wire breakage in the crimped barrel, the wire pulling out of the crimped barrel, or wire breakage outside of the crimped area. The method and device used to conduct this test have a direct bearing on the results obtained. Per specification, the testing device pulls at the rate of one inch per minute. During the tensile test, the wire is elongating. The breakage or separation point, therefore is associated with not only the pull force but also the rate of increase of this force.

Tensile curves are plotted for each contact and wire combination. They will usually differ, depending on the type of wire, plating, size of wire, and variations in contact design and material. A desirable tensile range must be determined for each of these combinations.

MILLIVOLT DROP

Millivolt drop tests are performed across the crimp joint to determine the electrical characteristics. The test current is passed through the contacts and voltage drop is measured from a point on the shoulder of the contact to a point on the wire. Voltage drop values within the maximum allowable indicate a good electrical joint.

VISUAL INSPECTION

Each contact is inspected under a microscope to make certain the indenture does not crack or tear the base metal, or cause excessive distortion of the contact.

CONTROLLING CRIMP DEPTH

From the tensile curves a known crimp depth range is established. It is imperative, therefore, that the crimp tool settings be within the established tolerance.

To insure full closure of the tool handles and positive bottoming it is necessary that tools be cycle controlled. This is accomplished by the use of a precision ratchet device which releases the handles at the positive bottoming position within specification tolerances. This release point and positive bottoming are applicable to all contact sizes.

MEASURE CRIMP DEPTH (GAGING)

Too loose a crimp setting will result in wire pullout and high millivolt drop (high resistance). Too tight a setting will neck the wire strands causing low tensiles and wire breakage within the contact.

Positive bottoming tools can readily be gaged by selecting gage pins dimensioned to the end limits of the known crimp range of a given contact.

AXIAL DEFORMATION

During the crimping process considerable force is applied and material displacement takes place which may result in axial deformation of the contact. The following factors contribute to axial deformation of contacts:

- Contact material and contact hardness.
- Crimp pot wall thickness.
- Concentricity of conductor hole to O.D. of crimp barrel.
- If an insulation support is included on the contact, the concentricity of this support (I.D. and O.D.) with respect to the other diameters in the
- Crimp depth--the deeper the crimp the greater the possibility of contact bending, size of wire, bunching of strands, the lay of the conductors, plating or the use of solid conductor.
- The condition of the indenters--indenters which are not uniformly dimensioned or aligned or which have extreme variation in surface condition can cause contact bending.
- The condition of the crimping tool--a worn crimping tool can contribute to contact bending.
- Method of contact location and support--improperly supporting or positioning the contact in the tool can result in contact bending.
- Method of measuring axial deformation--we have found that this is one of the least understood items relating to the crimp tool specification.

CRIMPING FACTS

MIL-C-22520 is specific in defining and evaluating the axial deformation of contacts. This specification allows the following deformation:

Contact Size	Contact Deformation
20 & smaller	.011 TIR
16	.012 TIR
12	.012 TIR

The TIR allowed includes a maximum of .005 TIR assignable to the contact during its manufacture.

TIR is an abbreviation for Total Indicator Reading and is a measure of the total deviation from a true center line when the item being measured is rotated through 360°.

COMPRESSION FORCES:

Crimping compression forces are directly related to: A: Indentor Configuration; B: The Amount of Leverage in a Crimping Tool; C: Crimp Depth Required for Satisfactory Results; D: Contact Hardness and Contact-Conductor Combinations.

A: Indentor Configuration MS drawings are specific as to indenter configuration of the Class I crimping tool. It is possible to change the shape of the indenters to reduce frontal area and thus reduce crimping forces. If the reduction of compression forces was the only factor involved, as knife blade edge on an indenter, or a conical tip shape would be the most desirable configuration. But this would result in cracked contacts, damage to plating, high wire brittleness because of the concentrated stress of a small crimp area, and would also result in marginal tensile values.

B: The Amount of Leverage in a Crimping Tool Leverage or linkage systems could be devised to minimize the amount of crimp compression forces. Archimedes' old adage could apply here wherein he says, "Give me a place to stand and to rest my lever on and I can move the Earth." From a practical viewpoint, however, the geometry of Class I tools under MIL-T-22520 are specific in tool length and width.

C: Crimp Depth Required for Satisfactory Results Another way to reduce compression forces is to vary crimp depth. It is understandable that the less the indenters indent the lower the compression forces involved. On the other hand, if the tool does not indent as deeply as specified, the possibility exists that submarginal or marginal tensile values will result.

D: Contact Hardness and Contact-Conductor Combinations Contact material is definitely a factor contributing to high compression forces. Some contacts are made of hard material; some contacts have thick walls and some contacts are required to cover a range of conductors, all of which could involve high crimping forces. It is felt that an analysis of these conditions and an attempt to make them compatible with the crimping tool could facilitate the reduction of compression forces.

As can be seen from this brief review of crimping, many factors influence the effectiveness of a crimped joint. However, a good crimping tool compensates for many of these factors by providing proper crimp depths resulting in termination having high tensile strength, low millivolt drop, and minimum contact deformation. With the use of a well-engineered tool, crimping becomes one of the most reliable methods of wire termination.

CONTACT APPLICATIONS

TYPICAL CONTACT-TERMINAL APPLICATIONS

Both model 400 & 500 series accommodate insulated and non insulated Ring, Spade and Forked Terminals from 26-24 gage thru 250 MCM, wire range 28 gage thru 250 MCM. Refer to specification charts for individual models.

These series also accept Flag, Right Angle, Quick connects, In-line Splice, End caps and Battery Terminals.

Models within this series accept #23 thru 4/0 Pin and Socket Contacts, and #28 thru 4/0 wire.

Coaxial applications and wire ferrules are also accommodated.

Refer to specification charts for model applications.

Many dies are available for special electrical and non-electrical applications. Contact Pico for your application needs.

CRIMPING CONFIGURATIONS

There are many different types of crimps employed today. Both Series 400 & 500 tools are capable of producing a number of crimp configurations, ranging from 4-indent, 8-indent, Hex, Circular, Square and a variety of others.

The indentor crimp principle has been used to produce a variety of impressions, the most common being the "bathtub" and "octadent" (Eight Indentor Crimp).

The 8-indent configuration has been chosen by the Military for use in the M22520/23 tools.

CONTACT APPLICATIONS

INSULATED TERMINALS (IT) | NON-INSULATED TERMINALS (NIT)

There are three basic methods used in the manufacture of closed barrel style solderless terminals. These variations affect the selection of proper die assemblies and locators.

A: Terminal made from Flat Stock:

Flat stock terminals have a greater wall thickness than tube stock, solid stock or cold headed. Forming of flat stock into a round crimp barrel results in a seam down the longitudinal axis of the barrel. This seam is usually brazed. The die sets used with terminals, which have a seam, have a concave profile on the indenter that is aligned with the seam. The purpose of this concave profile is to capture the seam and prevent separation during the crimp process. There are several manufacturers of flat stock terminals. Among them are Amp, ETC, 3M, Ideal and Wearnes Hollingsworth Corp.

Non-Insulated Terminal - Tube Stock

NOTES

- In most cases the same locator will perform satisfactorily for **IT INSULATED** and **NIT NON-INSULATED** terminals, but a locator for a **TUBE** stock terminal will not work with a **FLAT** stock terminal.
- Special dies and locators are available for flag and right angle terminals. If you are in doubt, please contact Pico Corporation.

Contact Pico Corporation for proper die assemblies and locators for these terminal styles.

Non-Insulated Terminal - Flat Stock

Insulated Terminal - Flat Stock

B: Terminals made from Tube Stock:

Burndy and Thomas and Betts manufacture terminals in smaller sizes using both flat and tube stock (22-18 thru 12-10). Larger sizes are made from tube stock (8 thru 2/0). All four indentors in the die sets used with tube stock terminals are the same and produce four symmetrical indentations. These die sets are identified with a “-B” suffix.

PICO CORPORATION

500 SERIES PNEUMATIC CRIMPING TOOL

MULTI INDENT • CYCLE CONTROLLED • MEETS PERFORMANCE REQUIREMENTS OF MIL-C-22520

Patent No. 3,173,341 & 3,201,969

The most versatile crimping tool available today.

Models 500-EC, 500-D, 500-DEC and 500-D-1 are available from stock to handle No. 22 through 250 MCM.

Standard factory air pressure 80-125 psi (5-8.6 BAR) is now sufficient for all sizes.

Model 500 has the same safety cycling feature that is built into all of the Pico line of quality tools.

Optional **EC kit** available for models 500-D & 500-D-1. EC kit replaces internal valve system, decreasing cycle time from 8 sec/cycle to 2.5 sec/cycle.

Human engineered to prevent accidents.

For more information contact Pico or visit web: www.picotools.com

Features

- Pneumatic - Full Cycle
- Pin & Sockets, Solderless Terminals
- Crimps No. 22 thru 250 MCM
- Variety of Crimp Styles
- Interchangeable, Nonadjustable Die Heads
- No Operator Adjustments required
- Precision +.001/-001"
- Operates on Shop Air 80-125 PSI (5-8.6 BAR)
- Series 500: 31-39 lbs (14-17.7 kg)

INSULATED/NON-INSULATED TERMINALS & SPLICES

PIN & SOCKET CONTACTS

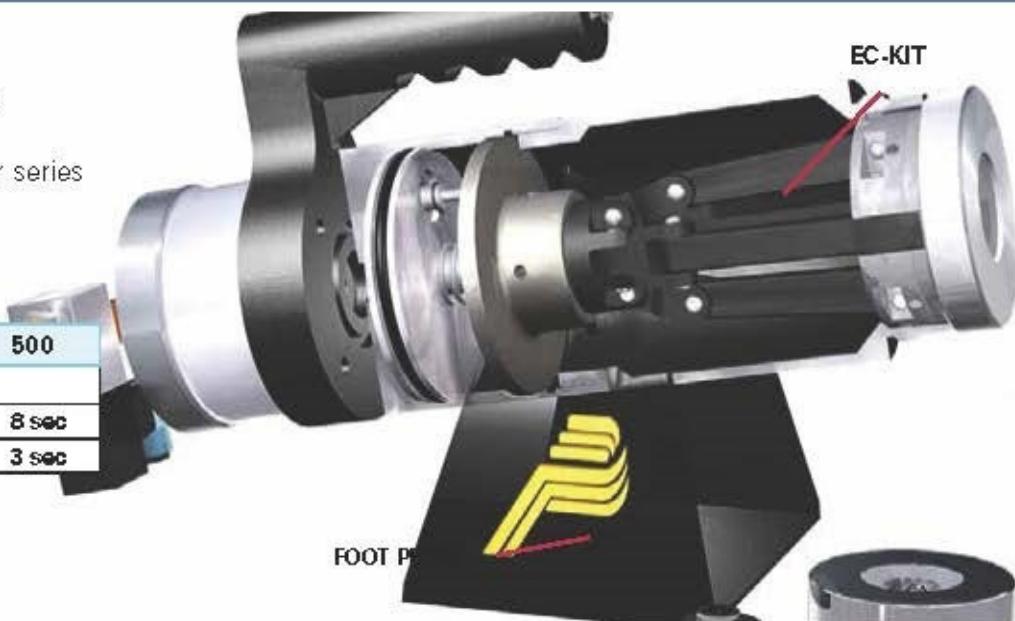

EC KIT

EC kit replaces internal valve system, decreasing cycle time over stock configuration, resulting in increased production rates.

Available as optional accessory for series 400, 400-BHD, 400-B-1, and series 500-D & 500-D-1.

Includes foot pedal.

SERIES MODEL	400	500
CYCLE TIME		
WITHOUT EC	3 sec	8 sec
WITH EC	1.5 sec	3 sec

ACCESSORIES

Several optional accessories are available, including:

Foot Pedal provides operator comfort and increased production speed with foot pedal cycle trigger.

Gaging tools, including Go No-Go gages for die calibration.

Portable Field Kit provides mobile power unit for field and in-plant applications. Kit includes CO₂ air tank - up to 400 crimps on a charge.

Contact Pico for additional details.

PORTABLE FIELD KIT

GO NO-GO GAGES
